Exercise 1

A *zero-phase* filter is a special case of a linear-phase filter in which the phase slope is 0. For a real-coefficient filter, the phase response only takes values of either 0 or π . Below, it is shown that the impulse response $h[n] = b_1\delta[n + 1] + b_0\delta[n] + b_1\delta[n - 1]$ leads to a *zero-phase* frequency response when $(b_0, b_1) \in \mathbb{R}^2$.

Starting out with the impulse response $h[n] = b_1\delta[n + 1] + b_0\delta[n] + b_1\delta[n - 1]$, the z-transform table can be used to convert it to the frequency response $H(z) = b_1z + b_0 + b_1z^{-1}$.

Input in $e^{j\omega}$ for z to find the frequency response:

$$H(e^{j\omega_c}) = b_1e^{j\omega_c} + b_0 + b_1e^{-j\omega_c}$$

Using Euler's identity $\cos(\theta) = \frac{e^{j\theta} + e^{-j\theta}}{2}$:

$$H(e^{j\omega_c}) = b_0 + b_1(e^{j\omega_c} + e^{-j\omega_c}) = b_0 + b_12\cos(\omega_c)$$

The real part of the equation is $b_0 + b_12\cos(\omega_c)$ and the imaginary part is 0. Using the formula for computing the phase response:

$$\angle H(e^{j\omega}) = \tan^{-1}\left(\frac{-0}{b_0 + b_12\cos(\omega_c)}\right) = \tan^{-1}(0) = 0$$

Exercise 2

Figure 1 is used for parts 1 to 4 and contains 3 graphs:

1. $x[n]$, a signal of the form $x[n] = (A + B\cos(\omega_0 n))u[n]$, where $u[n]$ is the unit step, and ω_0 is the normalized angular speed.
2. $y[n]$, the output of an FIR filter H of order M when $x[n]$ is the input to the filter.
3. A zoomed-in display of $y[n]$.

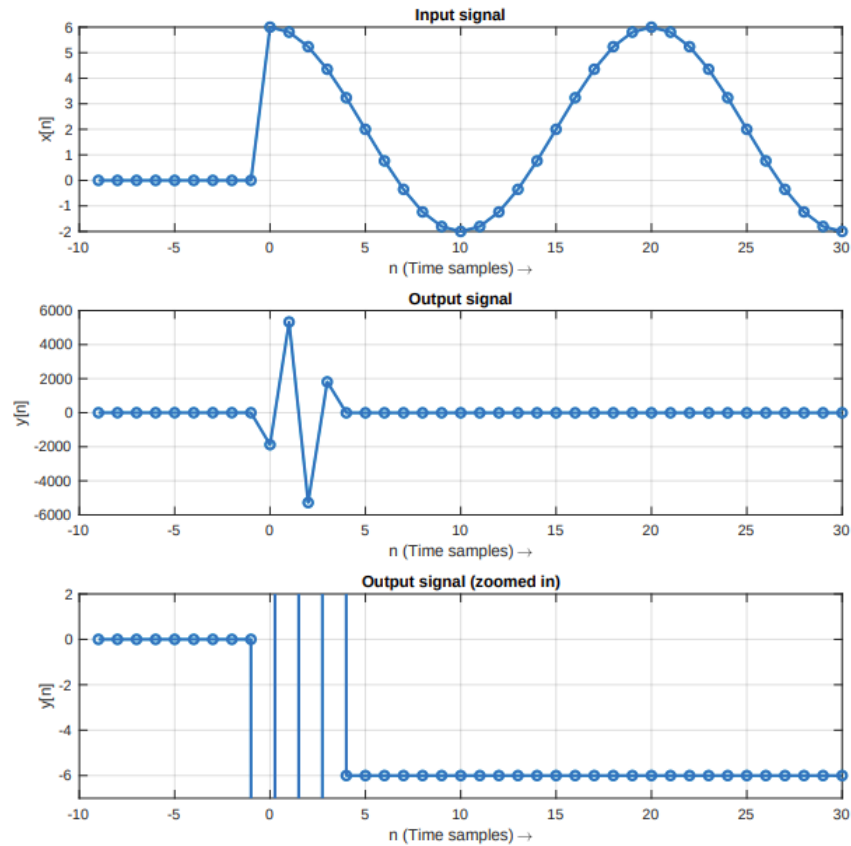

Figure 1: Input $x[n]$ and two views of the corresponding output $y[n]$ after filtering by system H .

Part 1: A, B, and Angular Speed

Using Figure 1, A is the DC offset which is the value around which the signal evolves (average of the signal). B is the amplitude of the signal which is the value after subtracting the DC offset. ω_0 is the unnormalized frequency which can be obtained by computing the relationship between the period obtained from the graph and the frequency $f = \frac{1}{T}$ and multiplied by 2π to normalize.

$$A = \frac{6 + -2}{2} = 2$$

$$B = 6 - 2 = 4$$

$$\omega_0 = \frac{2\pi}{20} = \frac{\pi}{10} \approx 0.314$$

Part 2: Order of the Filter

The order of an FIR is equivalent to the *warm-up* period duration (transient response). Using the Figure 1 to find the order M of the filter H , it is determined that $y[n]$ settles at the 4th sample. The filter is therefore of order $M = 4$.

Part 3: Zeros of the Transfer Function

The zeros of the transfer function $H(z)$ on the unit circle correspond to the locations where the frequency is filtered out. Observing the $y[n]$ output, the initial frequency is filtered output when the steady-state response is achieved. On the unit circle, there is therefore one zero and its conjugate. In polar form, the zero can be found at $re^{j\omega}$, where $r = 1$ because the zero is directly on the unit circle and $\omega = \frac{\pi}{10}$. The final value for the zero is

therefore $(1)e^{j\frac{\pi}{10}}$. There is also the conjugate zero which is in the same location but reflected over the Re axis such that $(1)e^{-j\frac{\pi}{10}}$. The two zeros are additionally expressed in cartesian form below.

$$\text{First zero: } e^{j\omega} = \cos(\omega) + j\sin(\omega) = \cos\left(\frac{\pi}{10}\right) + j\sin\left(\frac{\pi}{10}\right) = 0.951 + 0.309j$$

$$\text{Second zero: } e^{-j\omega} = \cos(-\omega) + j\sin(-\omega) = \cos\left(-\frac{\pi}{10}\right) + j\sin\left(-\frac{\pi}{10}\right) = 0.951 - 0.309j$$

Part 4: The DC Gain

The DC gain of a filter is the value of its frequency response where $\omega = 0$. In other words, DC gain is the ratio of the magnitude of the response to the steady-state step to the magnitude of the step input.

Magnitude of the steady-state

$$\lim_{n \rightarrow \infty} y_{\text{steady}}[n] = -6$$

Using the result found in part 1, where the $A = 2$, the ratio can be written as the below formula

$$DC_{\text{gain}} = \frac{1}{A} \lim_{n \rightarrow \infty} y_{\text{steady}}[n] = \frac{-6}{2} = -3$$

Exercise 3

Damping and bandwidth of a two-pole resonator are determined by the magnitude r of its complex poles

$p = re^{j\omega_c}$, and its complex conjugate \bar{p} . For example, it is possible to get the bandwidth B (in Hertz) of a resonator in terms of r with $B = -\frac{\ln(r)}{\pi T_s}$ where $T_s = \frac{1}{F_s}$ is the sampling period. This allows in return to calculate r in terms of bandwidth B , i.e. $r = e^{-\pi B T_s}$.

Part 1:

Considering a general two-pole filter defined by its resonant frequency $f_c = \frac{F_s}{4}$, and its bandwidth $B = 0.01F_s$.

Magnitude r

The magnitude r can be computed by plugging in the given values for B and T_s .

$$r = e^{-\pi B T_s} = e^{-\pi 0.01 F_s T_s} = e^{-\pi 0.01 F_s \frac{1}{F_s}} = e^{-\pi 0.01} = e^{-\pi 0.01 F_s T_s} = e^{-\pi 0.01} \approx 0.969$$

Angular Frequency ω_c

$$\omega_c = \frac{2\pi F_s}{F_s} = \frac{2\pi}{4} = \frac{\pi}{2} \approx 1.571 \frac{\text{radians}}{\text{sample}}$$

Transfer Function $H(z)$

$$H(z) = \frac{b_0}{(1 - pz^{-1})(1 - \bar{p}z^{-1})} = \frac{b_0}{(1 - re^{j\omega_c}z^{-1})(1 - re^{-j\omega_c}z^{-1})} = \frac{b_0}{1 - 2r\cos(\omega_c)z^{-1} + r^2z^{-2}} = \frac{b_0}{1 - 2e^{\pi 0.01}\cos(\frac{\pi}{2})z^{-1} + e^{-\pi 0.02}z^{-2}} = \frac{b_0}{1 - 0.939z^{-2}}$$

Since $\omega_c = \frac{\pi}{2}$, $\cos(\omega_c) = 0$, the equation can be further simplified:

$$H(z) = \frac{b_0}{1 - 1.938\cos(\frac{\pi}{2})z^{-1} + 0.939z^{-2}} = \frac{b_0}{1 + 0.939z^{-2}} \text{ where } a_1 = 0 \text{ and } a_2 = 0.939.$$

Part 2:

$$H(e^{j\omega_c}) = \frac{b_0}{1 + 0.939(e^{j\omega_c})^{-2}} = 1$$

$$b_0 = 1 + 0.939(e^{-2j\omega_c}) = 1 + 0.939(e^{-2j\frac{\pi}{2}}) = 1 + 0.939(e^{-j\pi}) = 1 + 0.939(\cos(-\pi) + j\sin(-\pi)) = 1 + 0.939(\cos(-\pi)) = 1 - 0.939$$

Part 3:

The frequency response of this filter is $H(e^{-j\omega_c}) = \frac{0.0610}{1 + 0.939e^{-2j\omega_c}}$

Magnitude Response

$$|H(e^{-j\omega_c})| = \frac{0.0610}{1 + 0.939e^{-2j\omega_c}} = \frac{0.0610}{1 + 0.939e^{-2j\frac{\pi}{2}}} = \frac{0.0610}{1 + 0.939(\cos(-\pi) + j\sin(-\pi))} = \frac{0.0610}{1 + 0.939(\cos(-\pi))} = \frac{0.0610}{1 - 0.939} = \frac{0.0610}{0.0610} = 1$$

Give magnitude and and phase response in general formula. and then plug in the values

Phase Response

Starting from the frequency response

$$H(e^{j\omega_c}) = \frac{b_0}{1 + a_1e^{-j\omega_c} + a_2e^{-2j\omega_c}} = \frac{b_0}{1 + a_1\cos(-\omega_c) + a_1j\sin(-\omega_c) + a_2\cos(-2\omega_c) + a_2j\sin(-2\omega_c)}$$

Using the odd/even property of sin and cosine function $H(e^{j\omega_c})$ can be simplified:

$$H(e^{j\omega_c}) = \frac{b_0}{1 + a_1\cos(\omega_c) - a_1j\sin(\omega_c) + a_2\cos(2\omega_c) - a_2j\sin(2\omega_c)} = \frac{b_0}{1 + a_1\cos(\omega_c) + a_2\cos(2\omega_c) - a_1j\sin(2\omega_c) - a_2j\sin(2\omega_c)}$$

Using the imaginary and real parts the of the frequency response:

$$\angle H(e^{-j\omega_c}) = \tan^{-1} \left(\frac{-(-a_1\sin(\omega_c) - a_2\sin(2\omega_c))}{1 + a_1\cos(\omega_c) + a_2\cos(2\omega_c)} \right) = -\tan^{-1} \left(\frac{-a_1\sin(\omega_c) - a_2\sin(2\omega_c)}{1 + a_1\cos(\omega_c) + a_2\cos(2\omega_c)} \right)$$

Plugging in the values for a_1 and a_2 :

$$\angle H(e^{-j\omega_c}) = -\tan^{-1} \left(\frac{-0 * \sin(\frac{\pi}{2}) - 0.939 * \sin(\frac{2\pi}{2})}{1 + 0 * \cos(\frac{\pi}{2}) + 0.939 * \cos(\frac{2\pi}{2})} \right) = -\tan^{-1} \left(\frac{-0.939 * \sin(\frac{2\pi}{2})}{1 + 0.939 * \cos(\frac{2\pi}{2})} \right) = -\tan^{-1} \left(\frac{-0.939 * 0}{1 + 0.939 * -1} \right) = -\tan^{-1} \left(\frac{0}{0} \right)$$

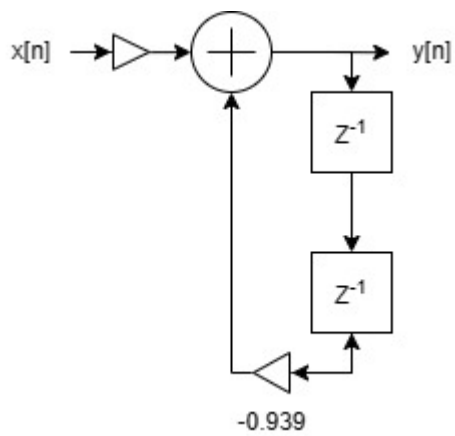

Part 4:

The two-pole filter can be defined by the following difference equation: $y[n] = b_0x[n] - a_1y[n-1] - a_2y[n-2]$.

Where $a_1 = 0$ and $a_2 = 0.939$ so the difference equation becomes $y[n] = 0.0610x[n] - 0.939y[n-2]$.
